

View in Asp.Net Core

Achyut V. Kendre

Today's Learning.

- What is View?
- How to Return View from Action?
- What is View Engine?
- Razor Syntax to Generate View.

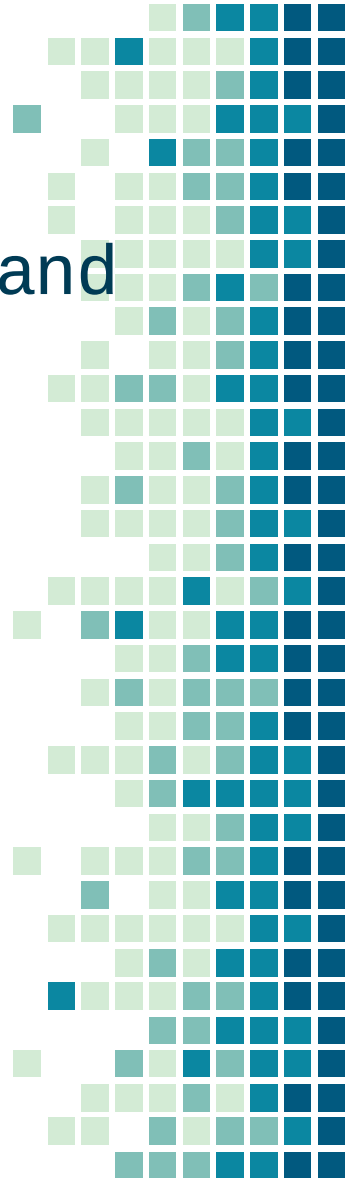

What is View?

- View is Responsible for UI Part/Presentation of MVC Application.
- View is just file located in Sub folder under Views folder contains UI Code (HTML, CSS, Scripts etc.).
- For every Controller ASP.NET MVC Creates a Sub Folder under views folder having same name as that of controller name.
- A View can contain “HTML/CSS/Images/Java Script” and “C#/VB” code.

What is View?

- It is a combination of C# /VB (server side code) and Html, CSS, Images, Scripts (Client Side Code).
- View File can have extension .cshtml/.vbhtml.

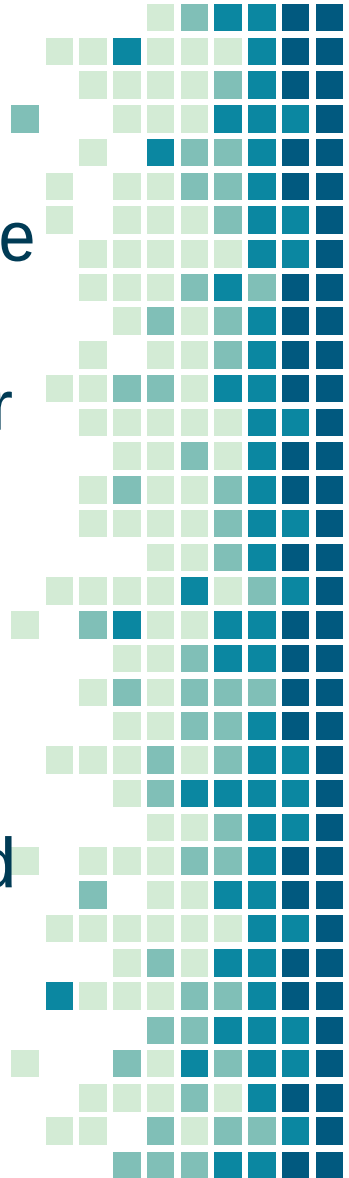

How to return View?

- Action can return a view if return type of the action is ViewResult or ActionResult.
- You can return view using –
- View() :- It will return a view having same name as that of action name from a folder whose name is exactly similar to controller class name located under views folder.

How to return View?

- View(“viewname”):- It will return a view whose name is passed as parameter in a folder whose name is similar to controller name located under views folder.
- If view file not found as per above rule, it will search it in shared folder.
- Shared Folder:- Shared folder is built in folder contains common views or views those supposed to be shared between multiple controllers and actions.

What is View Engine?

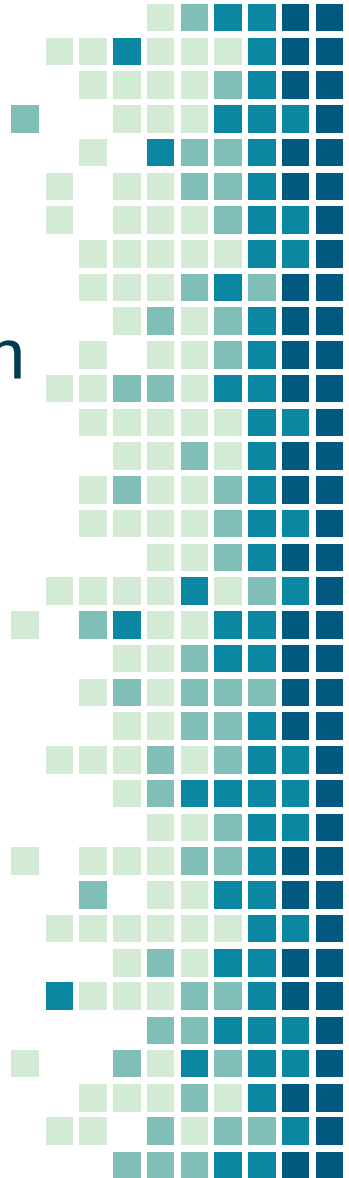

- View Engine in ASP.NET Core is a crucial component responsible for rendering a web page's user interface (UI) or presentation layer.
- Major work of View Engine is to convert/translate server code written in View to HTML/CSS and load it in browser. Beside this view engines facilitates template generation, model creation.
- By default ASP.Net Core supports Razor View Engine.

Razor Syntax

- Indirectly we can say Razor view engine provides you some commands /syntax using which we can embed server side code in a View.
- Razor syntax is a powerful feature in ASP.NET Core that allows you to embed .NET-based code directly into View.
- Comments: In Razor Syntax we can write comments.

@* comments *@

Razor Syntax

- Inline Expressions: Start with the @ symbol to write server-side C# or VB code alongside HTML. For example:
`<p>Current date and time: @DateTime.Now</p>`
- Multi-Statement Code Blocks: Enclose multiple lines of server-side code within curly braces ({ ... }).
- These blocks can manipulate models, declare variables, and set local properties on a view.

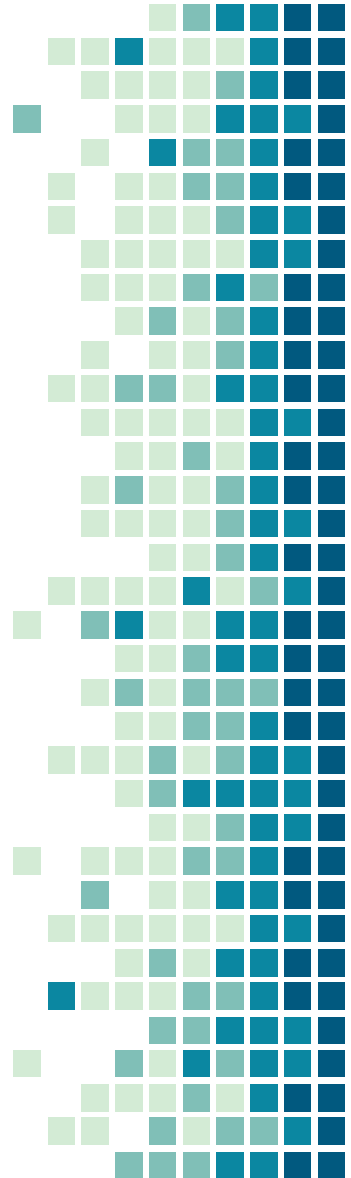

Razor Syntax

- Avoid using them for business logic.

```
@{  
    var message = "Hello, Razor!";  
    // Other statements here  
}
```

- Displaying Text from Code Blocks: Use @: or <text> to display text within a code block.

```
<p>@message</p>
```

THANKS!
