

Data Communication from Action to View

1. ViewBag
2. ViewData
3. TempData
4. Model

Action to View

- Controller action will process your request and invokes a view to create the presentation of result of action.
- Since action and view are decoupled from each other and action is method and view is file we need some intermediate arrangement to communicate data from action to view, so we need -
 - ViewBag
 - ViewData
 - TempData
 - Model

What is View Bag?

- Communicate data from action to view (One Way).
- Communicate small data from action to view.
- View Bag is Dynamic object you can create any name/type property.
- In action write data in view bag and in a view read view bag data.
- ViewBag will be empty when you redirect from one action to another.

ViewBag.Propertyname=value;

What is View Data?

- Communicate data from action to view (One Way).
- Communicate small data from action to view.
- View Data is Dictionary object collection (key value pair)
- We write data in action and read it from view.
- View Data will be empty when you redirect from action.
- ViewData is more faster than view bag.
- **ViewData["name"]=value**

What is Temp Data?

- Temp Data Communicate data from action to view (One Way).
- Used to Communicate small data from action to view.
- It is again Dictionary object collection (key value pair).
- Temp Data will maintain the data after redirects.

`TempData["name"]=value`

What is Model?

- In MVC M stands for model, model is responsible for data part of application.
- Model is used for various data related activities like - shaping data, retrieving data , validation or any data related logic.
- Model is also used to Communicate data from action to view or view back to action (Two Way).
- Model Communicate large/structured data from action to view.

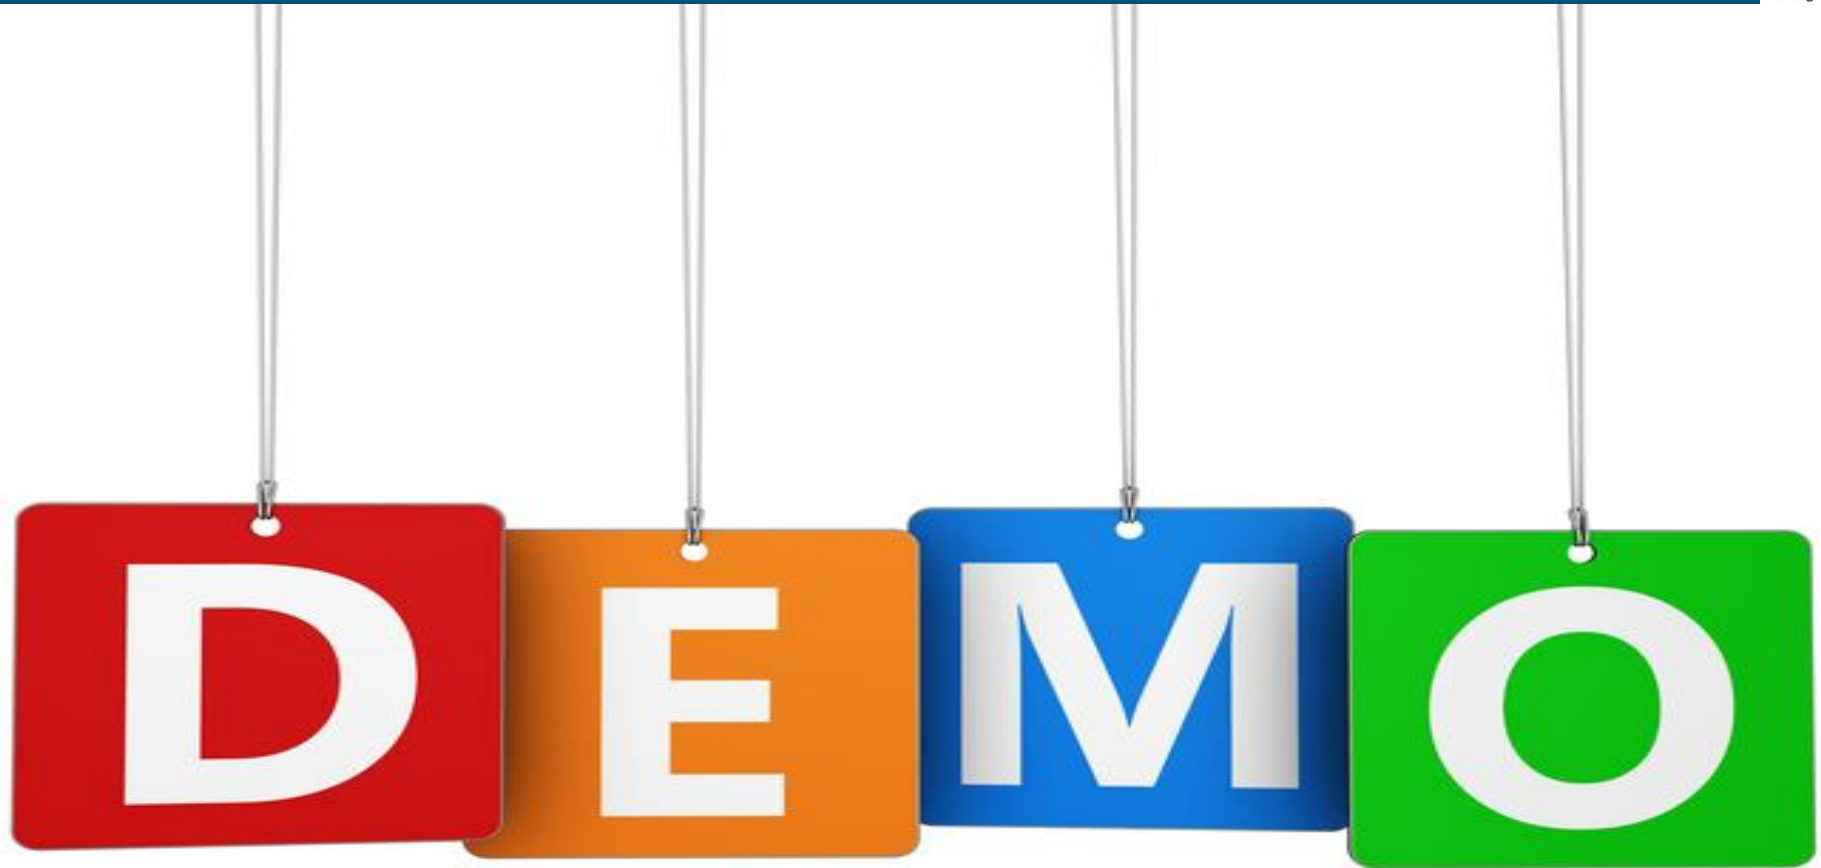

What is Model?

- Communicate Strongly typed data, from action to view.
- Practically Model is just class located in models folder which contains data related code/data logic.
- You can communicate model from action to strongly typed view.
- Strongly typed view is view connected with some model, show can access data from model object passed as parameter.

What is Model?

- You can create a strongly typed view using @model directive with full path of model class.
- Strongly typed view provides you built in property called @Model which get access to model object/data passed to a view.
- Action can return or invoke the strongly typed view using View(model), View(name, model).

ViewBag, ViewData, TempData & Model
